

#### Lorentzian Peak on Quadratic Background

# Big data en el CERN y otros contextos

Jhovanny Andres Mejia Guisao UNIVERSIDAD DE ANTIOQUIA, COLOMBIA

### **Motivation**

### What we hope to discuss about scientific data analysis?

- Advanced graphical user interface
- Interpreter for the C++ programming language
- Persistency mechanism for C++ objects
- Used to write every year petabytes of data recorded by the Large Hadron Collider experiments

Input and plotting of data from measurements and fitting of analytical functions.

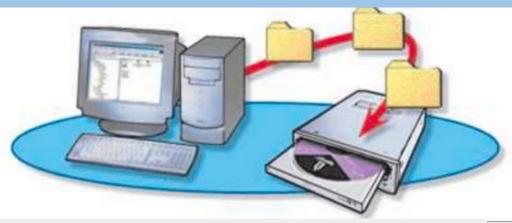

### Input/Output

```
void write_to_file(){
 // Instance of our histogram
 TH1F myh("myh","myh",100,-5,5);
 // Let's fill it randomly
 myh.FillRandom("gaus");
 // Let's open a TFile
 TFile out file("my rootfile.root","RECREATE");
 // Write the histogram in the file
 myh.Write();
 // Close the file
 out_file.Close();
```

```
root -I my_rootfile.root
root [0]
Attaching file my_rootfile.root as _file0...
root [1] _file0->ls();
TFile** my_rootfile.root
TFile* my_rootfile.root
KEY: TH1F myh;1 myh
root [2] myh->Draw();
```

```
example2_Read_from_file.C
```

### Interlude: I/O on cpp

```
-fstream archivoClientesEntrada( "clientes.txt",
ios::in );
```

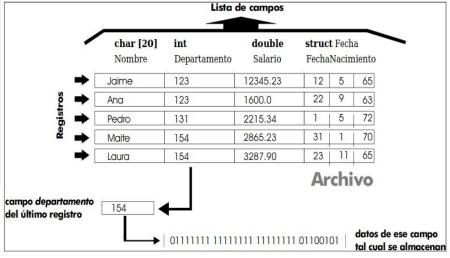

-ifstream archivoClientesEntrada( "clientes.txt" );

```
string name_file = "clientes.txt"; // txt, tex, dat, etc
ifstream archivo_entr;
archivo entr.open(name file.c str());
```

Prior to C++11, the filename was specified as a pointer-based string—as of C++11, it also can be specified as a string object.

```
#include<iostream>
#include<fstream>
#include<cstdlib>
#include<string>

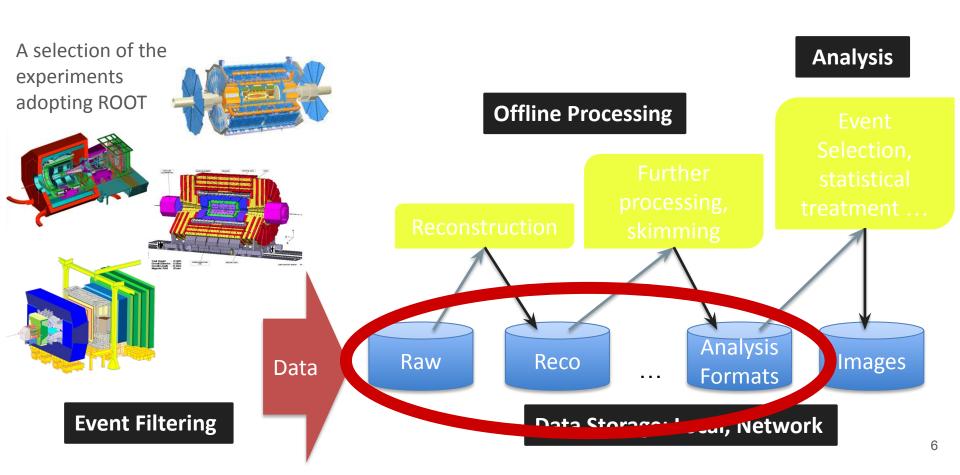

int main()
{
   cout << "xxxxxxxx"<< endl;
   return 0;
}</pre>
```

## **Learning Objectives**

- Understand the relevance of I/O in scientific applications
- Grasp some of the details of the ROOT I/O internals
- Be able to write and read ROOT objects to and from ROOT files

## I/O at LHC: an Example

## More Data in The Future?

Now	1 EB of data, 0.5 million cores
Run III	LHCb 40x collisions, Alice readout @ 50 KHz (starts in 2022 already!!)
HL-LHC	Atlas/CMS pile-up 60 -> 200, recording 10x evts

### The ROOT File

- In ROOT, objects are written in files\*
- ROOT provides its file class: the TFile
- TFiles are binary and have: a header, records and can be compressed (transparently for the user)
- TFiles have a logical "file system like" structure
  - e.g. directory hierarchy
- TFiles are self-descriptive:
  - Can be read without the code of the objects streamed into them
  - E.g. can be read from JavaScript

<sup>\*</sup> this is an understatement - we'll not go into the details in this course!

### TFile in Action

```
TFile f("myfile.root", "RECREATE");
TH1F h("h", "h", 64, 0, 8);
h.Write();
f.Close();
```

Option	Description		
NEW or CREATE	Create a new file and open it for writing, if the file already exists the file is not opened.		
RECREATE	Create a new file, if the file already exists it will be overwritten.		
UPDATE	Open an existing file for writing. If no file exists, it is created.		
READ	Open an existing file for reading (default).		

## The *gDirectory*

### Wait! How does it know where to write?

- ROOT has global variables. Upon creation of a file, the "present directory" is moved to the file.
- Histograms are attached to that directory
- Has up- and down- sides
- Will be more explicit in the future versions of ROOT

```
TFile f("myfile.root", "RECREATE");
TH1F h("h", "h", 64, 0, 8);
h.Write();
f.Close();
```

### More than One File

### Wait! And then how do I manage more than one file?

- You can "cd" into files anytime.
- The value of the gDirectory will change accordingly

```
TFile f1("myfile1.root", "RECREATE");
TFile f2("myfile2.root", "UPDATE");
f1.cd(); TH1F h1("h", "h", 64, 0, 8);
h1.Write();
f2.cd(); TH1F h2("h", "h", 64, 0, 8);
h1.Write();
f1.Close(); f2.Close();
```

## Listing TFile Content

- *TFile::ls()*: prints to screen the content of the TFile
  - Great for interactive usage
- TBrowser interactive tool
- Loop on the "TKeys", more sophisticated
  - Useful to use "programmatically"
- rootls commandline tool: list what is inside

```
TFile f("myfile1.root");
for (auto k : *f.GetListOfKeys()) {
    std::cout << k->GetName() << std::endl;
}</pre>
```

### Let's do some examples

```
root [0] TFile* f = new TFile ("myfile1.root", "READ");
root [1] if (f->IsOpen () == true) cout << "File open.\n";
root [2] f->ls();
root [4] TH1F* h = new TH1F ("h", "myhisto", 10, 0., 10.);
root [5] h->Write ();
root [0] TFile* f = new TFile ("myfile.root", "UPDATE");
root [1] f->ls();
root [2] TH1F* hr = (TH1F*) f-> Get ("myh1");
root [3] hr->Draw();
root [4] TH1F* myh3 = new TH1F ("myh3", "myh3", 100, 0., 10.);
root [5] TRandom3 r; r.SetSeed();
root [6] for (int i=0; i<1e5; i++) myh3->Fill ( r.Gaus(5,1) );
root [7] myh3->Write ("h copy");
root [8] f->ls();
root [9] f->Close();
```

### Example3\_files.C

- -Setting up the work directory on a disk
- -Execution of Linux command

```
root [0] gSystem->pwd ()
root [1] gSystem->cd ("../")
root [2] gSystem->pwd ()
root [3] gSystem->Exec ("date")
root [4] TString datenow = gSystem->GetFromPipe ("date");
root [5] datenow
root [6] TString datenow2(datenow(0,6))
root [7] TString datenow3(datenow(6,11))
```

## Hierarchy of objects in Root files and memory

```
root [1] gDirectory->pwd();
root [2] TFile f1 ("my_rootfile.root");
root [3] cout << gDirectory->GetPath () << endl;
root [4] .ls</pre>
```

Creating subdirectories (in memory or inside a .root file)

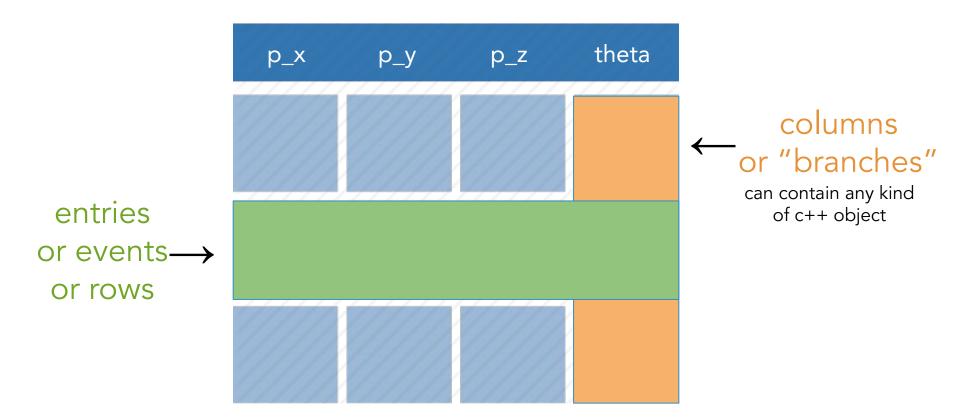

```
root [6] TFile f2 ("newfile.root", "RECREATE")
root [7] .ls
root [8] gDirectory->mkdir ("folder1");
root [9] .ls
root [10] gDirectory->cd ("folder1");
root [11] .pwd
root [12] TH1F h ("myhisto", "", 10, -5., 5);
root [13] TRandom3 r; r.SetSeed();
root [14] for (int i=0; i<1e5; i++){ h.Fill ( r.Gaus() );}
root [15] h.Write();
root [16] .ls
```

```
root [18] gDirectory->cd ("..");
root [19] .ls
root [20] gDirectory->rmdir ("folder1")
root [21] .ls
root [22] f2.Close ();
root [23] .ls
root [24] cout << gDirectory->GetPath() << endl;
root [25] gDirectory->cd ("Rint:/");
root [26] .ls
root [27] gDirectory->pwd();
```

### The ROOT Columnar Format

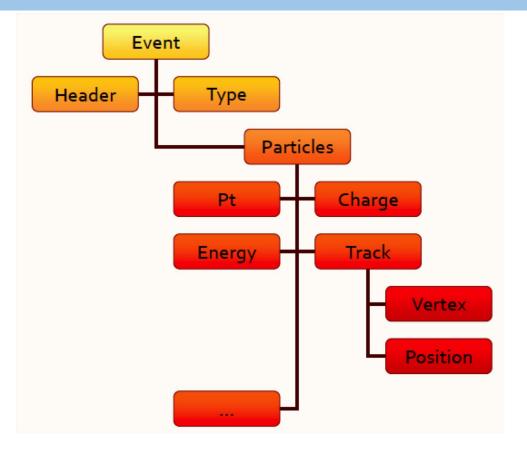

- High Energy Physics: many statistically independent collision events
- Create an event class, serialise and write out N instances on a file? No. Very inefficient!
- Organise the dataset in columns

## Columnar Representation

## Relations Among Columns

Х	у	z

### **TTree**

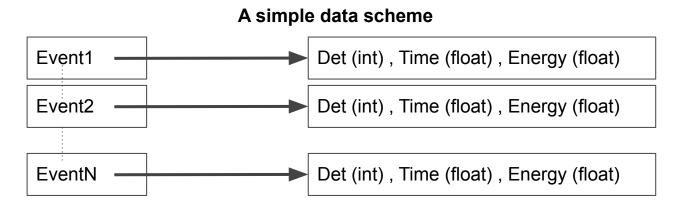

A columnar dataset in ROOT is represented by **TTree**:

- Also called tree, columns also called branches
- An object type per column, any type of object
- One row per entry (or, in collider physics, event)

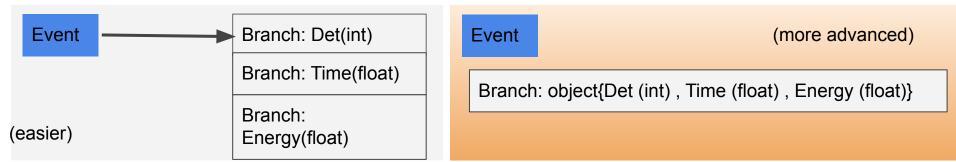

If just a **single number** per column is required, the simpler **TNtuple** <u>can</u> be used.

### TTree

Eg. experiment measuring particles in telescopes: set of  $N_i$ ,  $T_i$ ,  $\Delta E_i$ ,  $E_i$  from a detector (detectors) Eg. experiment measuring tracks of particles in drift chambers: set of px , py , pz ,  $\Delta E_i$  from a chamber

### Possible event structures:

## N-tuples in ROOT

TNtuple object can store rows of float entries

```
example4_write_ntuple_to_file.C example5_read_ntuple_to_file.C
```

Open the ROOT file (conductivity\_experiment.root) written by the macro above in an interactive session and use a TBrowser to interactively inspect it:

```
root [1] TBrowser II
(TBrowser &) Name: Browser Title: ROOT Object Browser
root [2] cond_data->Draw("Current:Potential")
root [3] cond_data->Draw("Current")
root [4] cond_data->Draw("Potential")
root [5] cond_data->Draw("Current:Potential","Temperature<270")
root [6] cond_data->Draw("Current/Potential:Temperature")
```

## TTrees and TNtuples

- TNtuple is great, but only works if columns hold simple numbers
- If something else needs to be in the columns, TTree must be used
- ► TNtuple is a specialisation of TTree

We explored how to read TTrees starting from the TNtuple examples

### TTree: Simplest way to create a tree from data in text file

### MyExpData.txt: They are in 3 columns (int, float, float)

```
Let's open the TTree object and fill the
                                                int Example6 myTtree fromfile()
database with data using the ReadFile
                                                  TFile f( "simplest tree.root", "RECREATE" );
method:
                                                  TTree t( "mytree", "Tree of data for my analysis");
ReadFile fills the tree from txt file-
                                                 t.ReadFile ("MyExpData.txt", "det/I:energy/F:time/F");
                                                 t.Print();
Print displays stats
                                                 t.Scan ("det:energy:time");
 Scan prints out data _
                                                 t.Draw ( "energy:time" , "det >= 7" );
Draw: en-time plot
 We set up filter on det
                                                  t.Write ();
Write saves tree in file
                                                 return 0;
 Example6 myTtree fromfile.C
```

## Now we'll design the tree by ourselves.

Scheme "1 branch = 1 variable"

#### **Define the branch:**

t.Branch ("Name", &variable,"variable/F");

List of variable types that can be used to define the type of a branch in ROOT:

type	size	C++	identifier
signed integer	32 bit	int	I
	64 bit	long	L
unsigned integer	32 bit	unsigned int	i
	64 bit	unsigned long	1
floating point	32 bit	float	F
	64 bit	double	D
boolean	-	bool	O

Example7\_myTtree\_fromfile.C Example7\_myTtree\_fromfile2.C

```
int TTree_simple () {
Int t det;
Float t energy, time;
TFile f ("simple.root", "RECREATE");
TTree t ("tree", "My tree");
t.Branch ("Det", &det, "det/I");
t.Branch ("En", &energy, "energy/F");
t.Branch ("Time", &time, "time/F");
TRandom3 r; r.SetSeed ();
for (int i = 0; i < 100; i++) {
det = r.Integer (24):
time = r.Rndm() * 20.;
energy = r.Rndm() * 30.;
t.Fill ();
t.Write (); Writing the tree in a file
return 0;
```

### Inspection of the tree in an interactive session

```
root -l --web=off ttree simple.root
root [2] tree->Print();
*Tree :tree : My tree
*Entries:
            100 : Total = 3213 bytes File Size =
                                                          1723
           : Tree compression factor = 1.20
*Br
     0 :Det
                  : det/l
*Entries: 100: Total Size= 947 bytes File Size =
                                                       231
*Baskets: 1: Basket Size=
                              32000 bytes Compression= 2.03
*Br
    1 :En
                  : energy/F

           1 : Basket Size=
                              32000 bytes Compression= 1.00
    2 :Time
                  : time/F
*Br
*Entries:
            100 : Total Size= 952 bytes File Size =
                                                       471
                              32000 bytes Compression= 1.00
*Baskets:
           1 : Basket Size=
root [3] tree->Show(10);
=====> EVENT:10
det
           = 23.3717
energy
time
            = 11.4525
```

```
root [4] tree->Scan();
      Row * Det.Det.d * En.En.ene * Time.Time
            16 * 19 158380 * 10 351733 *
            15 * 0.9651761 * 2.1733038 *
            21 * 17.750726 * 7.3583464 *
            22 * 10.996044 * 4.7895526 *
            8 * 4.5340204 * 17.619024 *
             15 * 10.425326 * 8.0490799 *
            11 * 20.414157 * 9.5272665 *
             16 * 2.7496554 * 2.2426822 *
            5 * 2.5598568 * 8.5067834 *
             10 * 7.9277925 * 6.5382695 *
```

### Plotting the histogram of a variable (variables, combination of variables, etc)

```
root -I --web=off ttree_simple.root
root [2] tree->Draw("En")
root [3] tree->Draw("sqrt(En)")
root [4] tree->Draw("time:energy","", "colz")
root [5] tree->Draw ("time:Entry$")

Example of function of variable
2-dimensional plot
Entry$ is a special keyword = entry
number
```

### Plotting the histogram of a variable with some filters (cuts) required

```
root [6] tree->Draw ("Time", "Det>14 && Det<23")
```

### Projection of variables from a tree to a histogram

```
root [7] tree->Project(
root [7] TH1F henergy ("henergy", "henergy", 15, 0., 30. );
root [8] tree->Project("henergy", "En", "Det<=10");
root [9] henergy.Draw();
```

### Cuts (TCut)

```
root [21] TCut cut3 ("Det>10"), cut4 = "Det<20"; root [22] tree->Project ("henergy", "En", cut3 && cut4); root [23] henergy.Draw();
```

One can combine TCut with string

root [9] tree->Draw ("energy", cut3 && "Entry\$ <= 50");

### Getting the TTree from the ROOT file + readout of data from TTree:

```
int TTree simple read () {
 Int t det;
 Float_t energy , time;
 TFile f ("simple.root");
 TTree^* t = (TTree^*) f.Get ("tree");
 t->SetBranchAddress ("Det", &det);
 t->SetBranchAddress ("En", &energy);
 t->SetBranchAddress ("Time", &time );
 for(int i=0; i<t->GetEntries(); i++)
     t->GetEntry (i);
     cout << setw( 5) << det
      << setw(12) << time
      << setw(12) << energy << endl;
 return 0;
```

```
Connect to the tree:
TTree* t = (TTree*) f.Get ("tree");
Connect the variables to the branches:
't->SetBranchAddress ("name",&variable);
Get the number of entries:
t->GetEntries();
Read the full event into the variables:
t->GetEntry (i);
```

### Merging data from ROOT files with the same structure

If we need to analyse a series of files with TTree that has the same structure, we can of course make a loop: open i-th file, connect the tree and branches, analyse data, and close that file. However, if we store the resulting histograms in a common output file, one often has to switch back and forth the gDirectory.

There is an alternative: merging the input data.

```
TChain. Object being effectively a queue of subsequent TTrees in specified files.

Let's assume that every input file has a TTree called "T".

TTree_simpleN.C

1. Create the TChain: TChain myChain ( "T" );

2. Add subsequent files: myChain.Add ( "file1.root");

myChain.Add ( "file2.root");

myChain.Add ( "file3.root");

3. Since now we use the myChain object, as if it was the common input tree.
```

```
The hadd executable, runnable from prompt:

> hadd data_merged.root data_1.root data_2.root .... (or: data_*.root)

Caution: Caution the maximum size of resulting file is set to 100 GB. For bigger data there is a TFileMerger class.
```
